2018 Hurricane Season in Review

- 15 named storms (normal = 12)
- 8 hurricanes (normal = 6)
- 3 category 3+
“Normal”: 2-3

Hurricane Michael

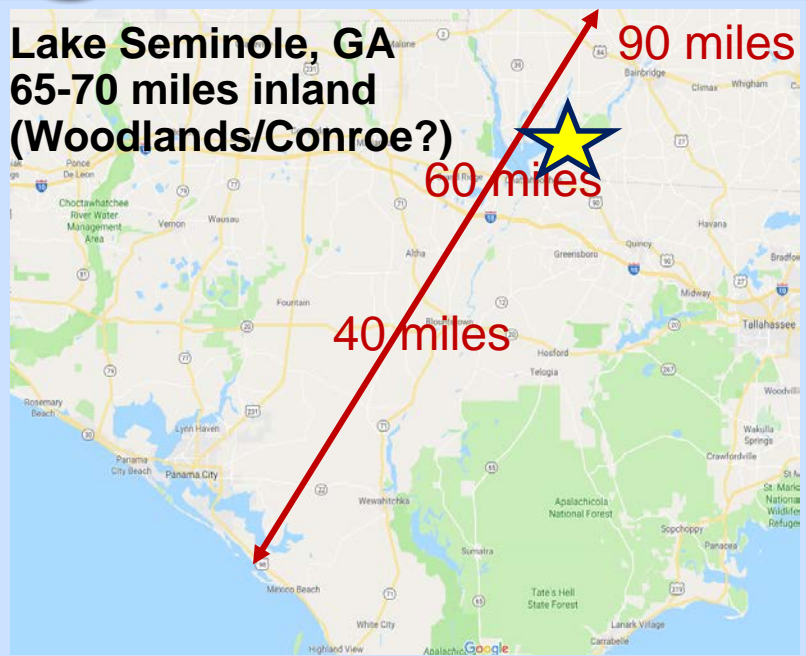

Only the fourth Category 5 storm to ever make landfall in the US mainland

- **Strongest winds at landfall since Andrew in 1992**
- **Deadly winds and storm surge along Florida panhandle; wind impacts well inland**
- **155-160 mph sustained peak winds...storm motion was fast so wind impacts well inland.**
- **9-14 foot storm surge.**

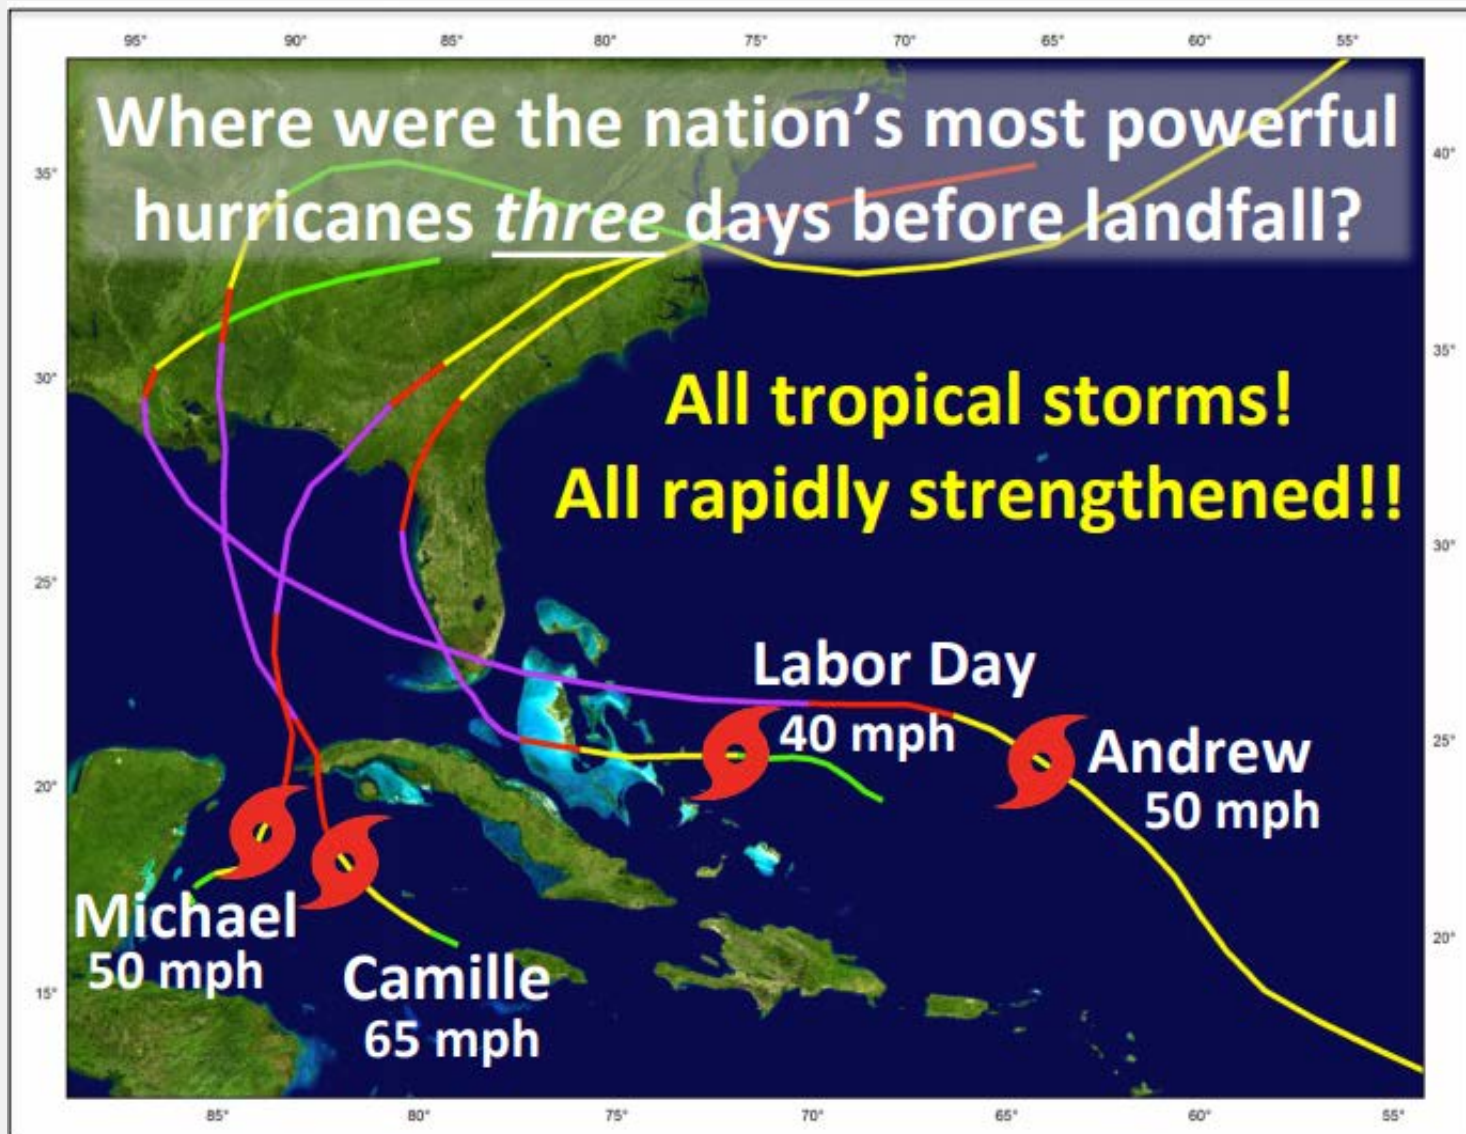

Michael - inland wind devastation

Beware of rapid strengthening

Tropical Outlook 2019

	30 year average	Colorado State	AccuWeather	WeatherBell	NOAA
Named Storms	12	13	12-14	10-15	9-15
Hurricanes	6	6	5-7	4-7	4-8
Category 3+	2-3	2	2-4	0-2	2-4

Notice how these don't tell you when, where, intensity or impacts?

It just takes one to make it a bad year!

2019 Names

2019 Atlantic Tropical Cyclone Names*

~~Andrea~~
~~Barry~~
 Chantal
 Dorian
 Erin
 Fernand
 Gabrielle

Humberto
 Imelda
 Jerry
 Karen
 Lorenzo
 Melissa
 Nestor

Olga
 Pablo
 Rebekah
 Sebastien
 Tanya

May 23, 2019

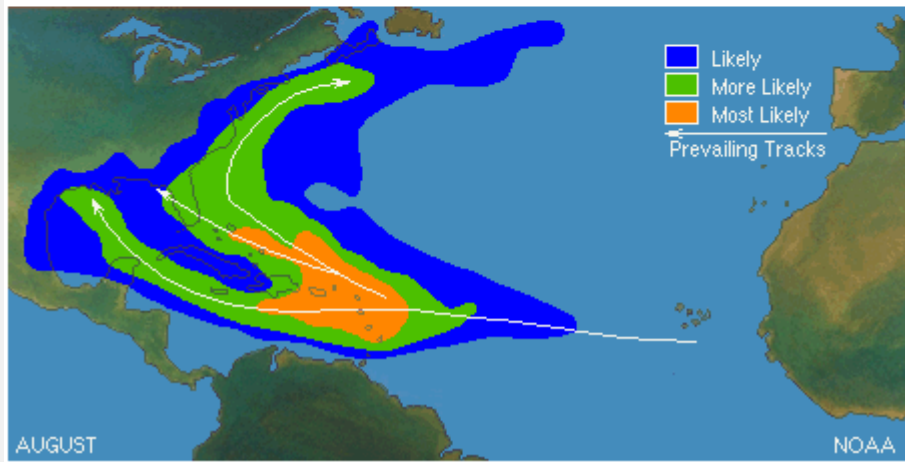

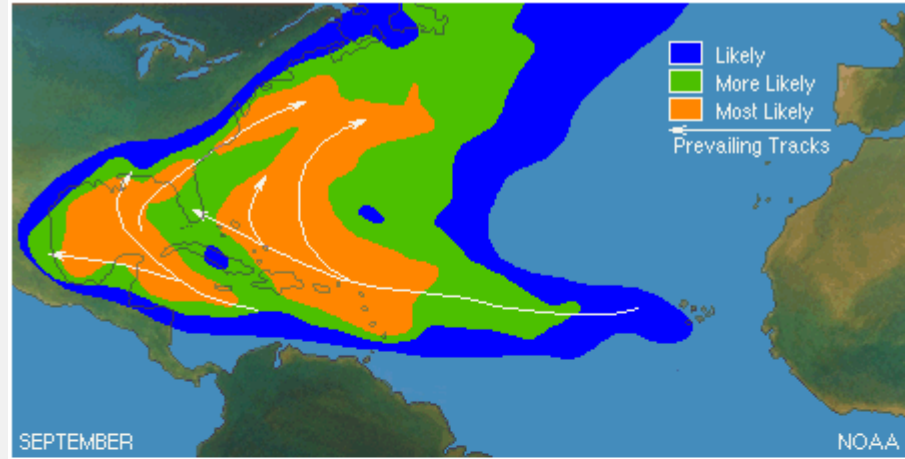

Average Hurricane Season: Running Totals

Typical Development Areas

Potential Hazards

Every storm will have a different set of hazards

Storm Surge Flooding

Ike (2008)
Carla (1961)

Tornadoes

Kendall Haynes

Buelah (1967)
Harvey (2017)

Damaging Winds

Alicia (1983)
Andrew (1992)
Camille (1969)
Carla (1961)

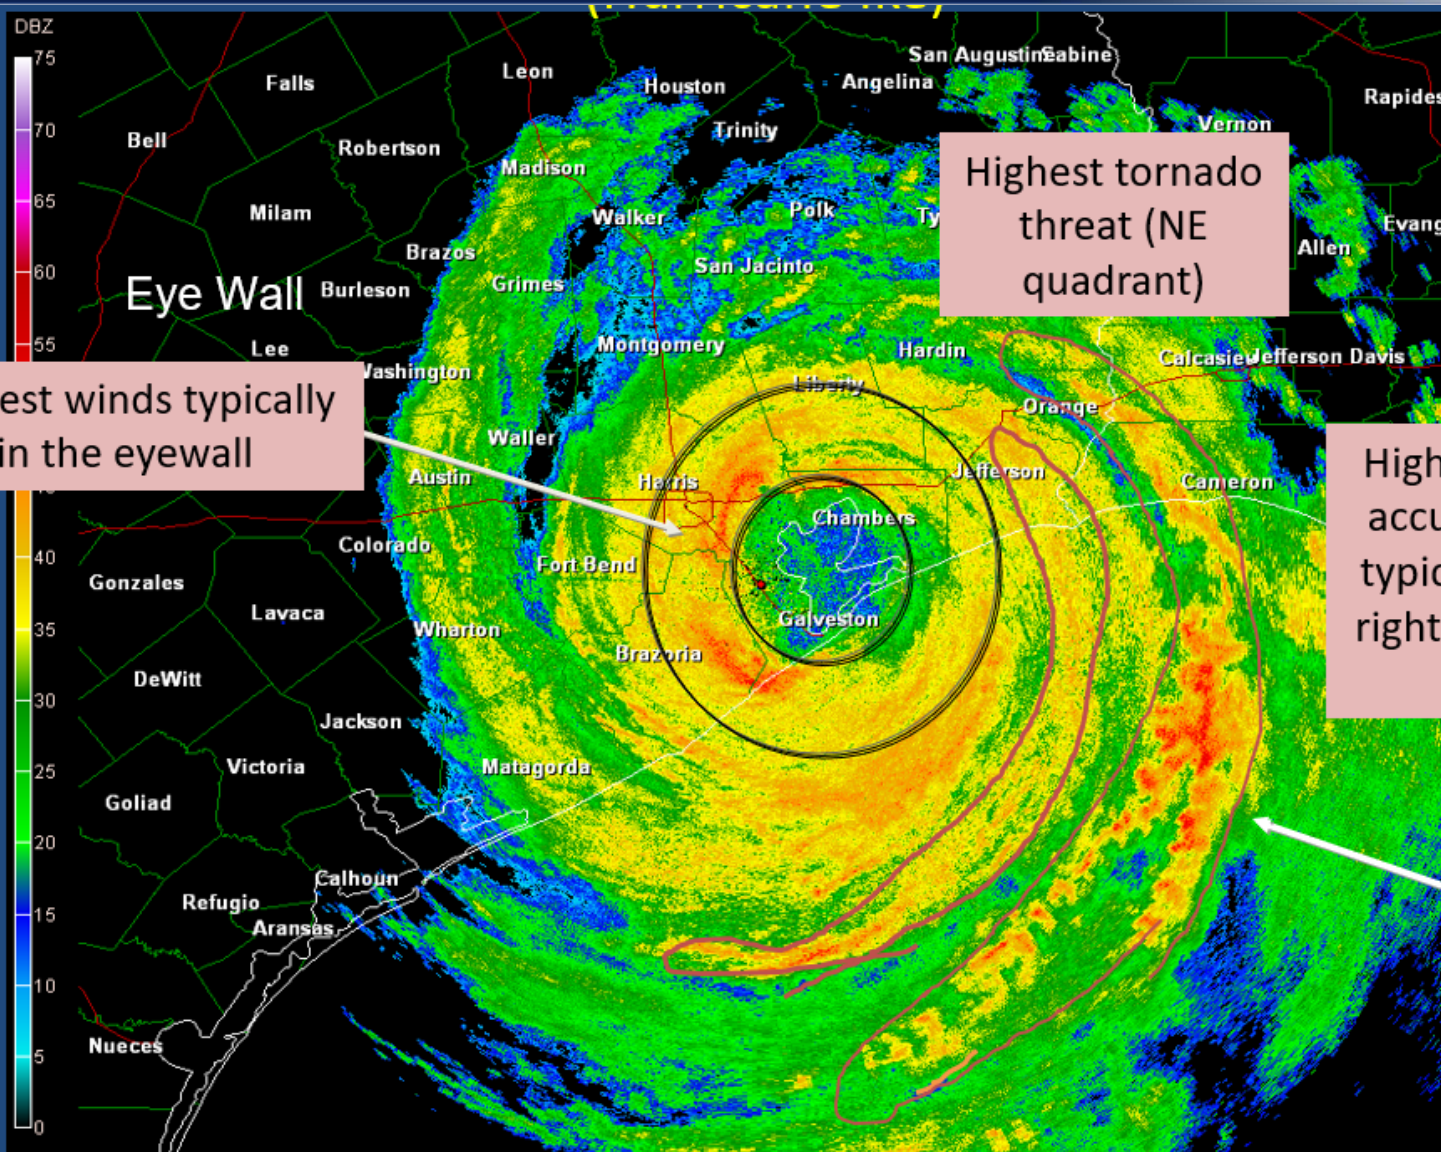

Flooding Rains

TS Allison (2001)
Harvey (2017)

Anatomy of a Hurricane (Ike)

Highest winds typically in the eyewall

Highest tornado threat (NE quadrant)

Highest rainfall accumulations typically on the right side of the storm

Gusty winds in spiral bands

The Saffir Simpson Hurricane Scale

It's only a WIND scale based on maximum sustained winds in hurricane.

Need to factor in all hazards (rain, surge, etc)!

Hurricane Wind Scale
@LookBermuda

Cat 1
74-95 mph

Cat 2
96-110 mph

Cat 3
111-129 mph

Cat 4
130-156 mph

Cat 5
157 mph or higher

Sense of Security?

Danger of directly comparing storms to highlight a threat

Allison (2001) vs. Harvey (2017) Total Rainfall

This area got less than 6 inches during Allison and 25-40 inches during Harvey

A similar argument can be made for wind speeds.

Tropical Cyclone Fatalities

Water is What KILLS!!!

U.S. Tropical Cyclone Fatalities
1963-2012

Water accounts
for about 90% of
the direct deaths

Rappaport 2014

Tropical Cyclone Fatalities

Water Continues to Kill

2016-18 Fatalities*

83% Water Related

Most Inland Flooding – Only 4% Storm Surge Related

*excludes Maria due to uncertainty related to causes of direct deaths

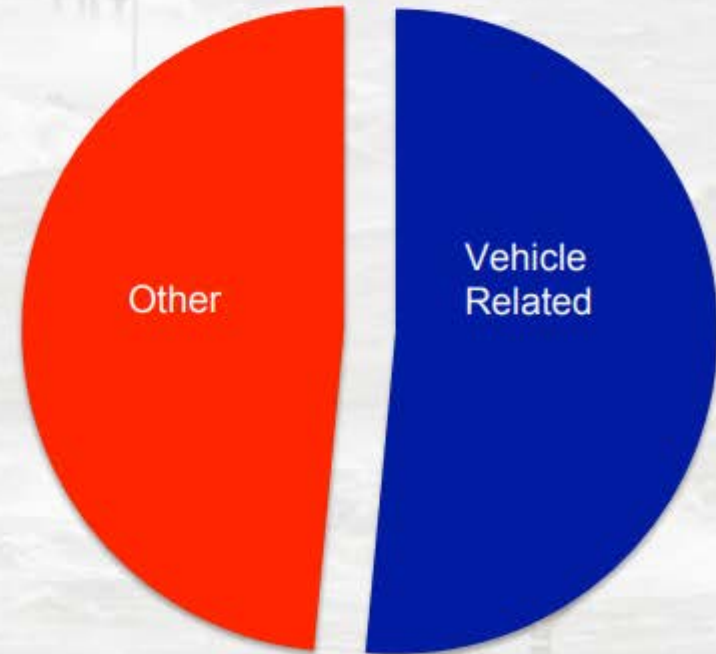

Tropical Cyclone Fatalities

Flood Related Vehicle Fatalities

- During the past three seasons, more than half the U.S. tropical cyclone water-related fatalities were vehicle related!

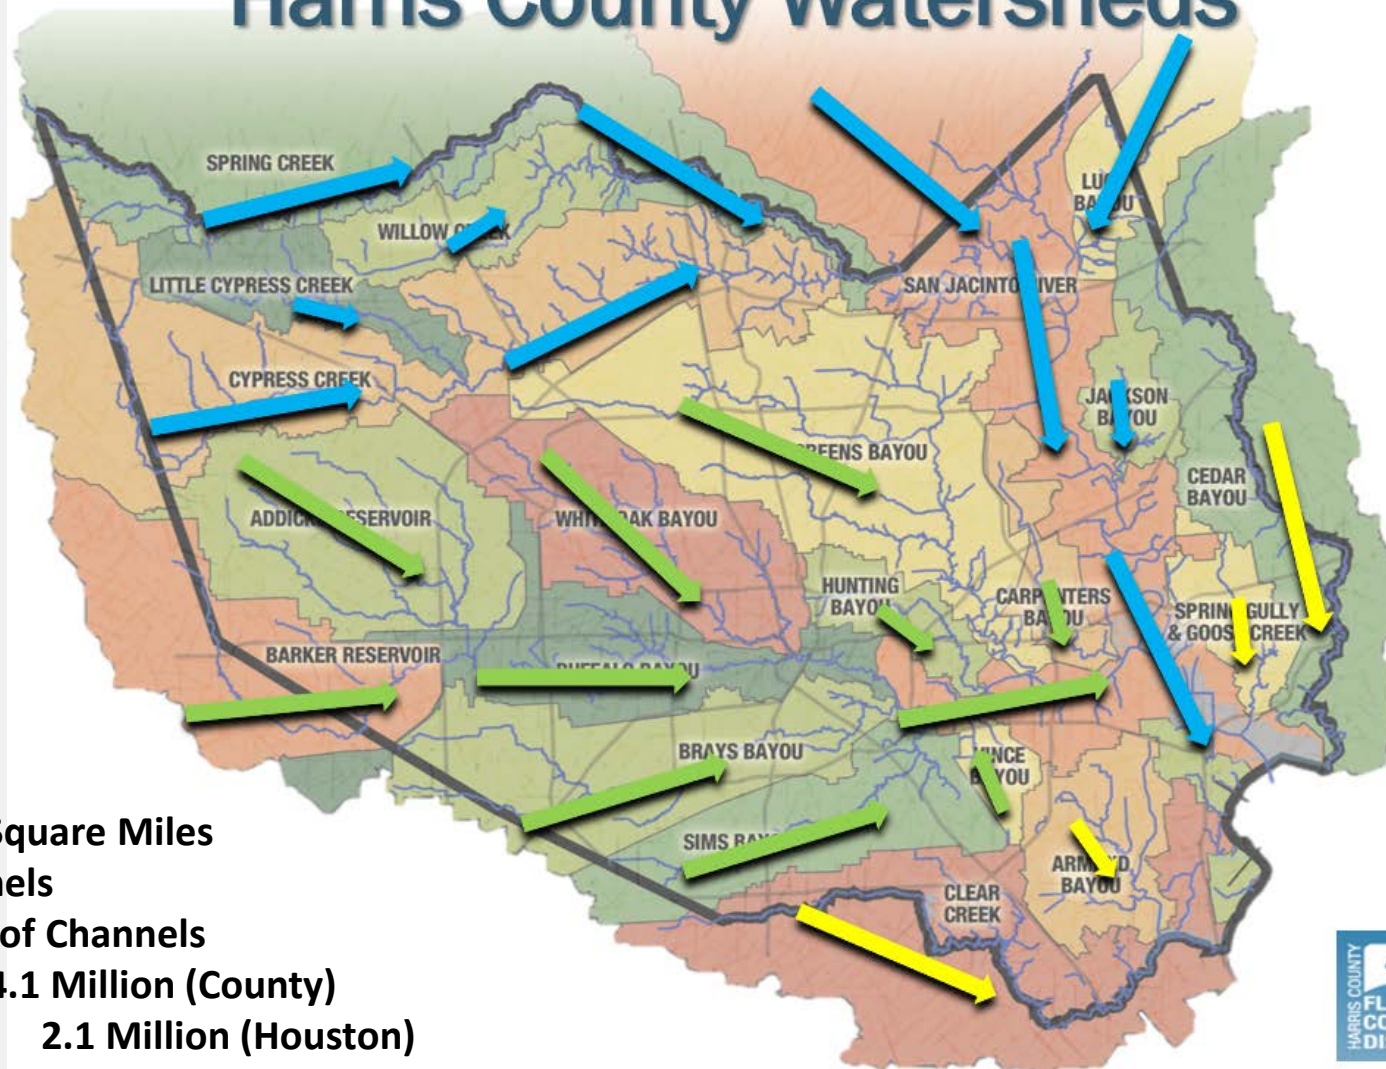

2016-18 U.S. Tropical Cyclone Water Related Fatalities

Watersheds & Rainfall

Harris County Watersheds

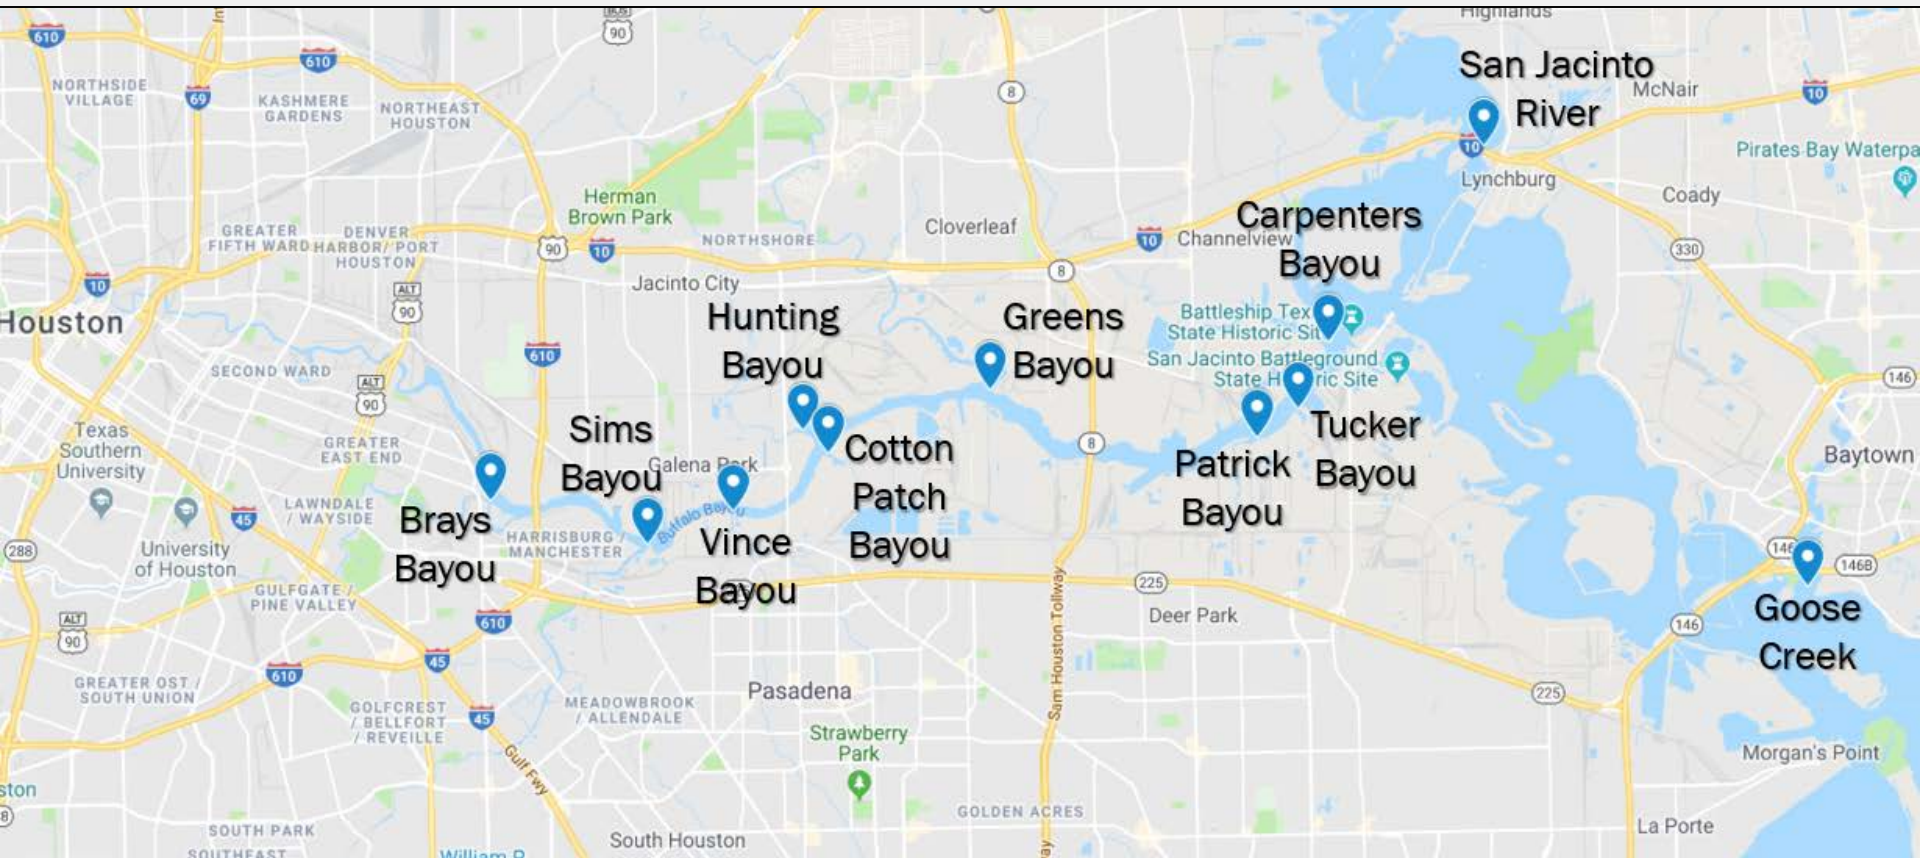

Area = 1,756 Square Miles
 ± 1,500 Channels
 ± 2,500 Miles of Channels
 Population = 4.1 Million (County)
 2.1 Million (Houston)

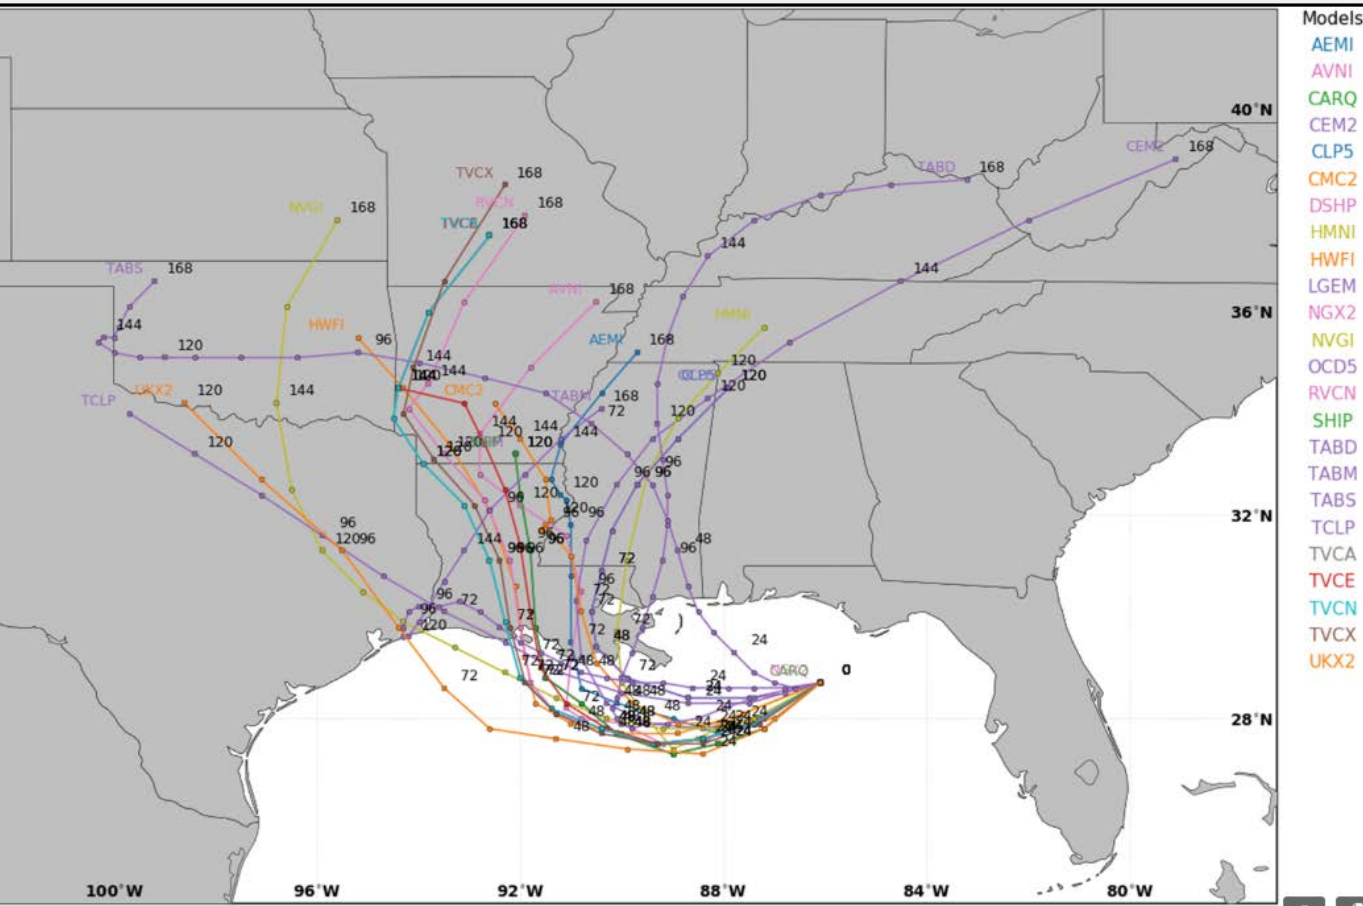

Ship Channel

Confluence Locations

Spaghetti Plots – Caution!

- Can be useful, but also may not be seeing the whole picture
 - Some of the best guidance isn't publicly available for proprietary reasons.
 - Many users might not have the forecaster's perspective and experience model strengths and weaknesses, trends, etc.

Track Model by Storm (2017)

Considerable variability from storm to storm, with no clear best model at 48-h across the board

EGRI: Gert, Harvey
 EMXI: Irma, Ophelia
 GFSI: Jose, Maria
 HWFI: Nate

5-day Track Model Trends (2001-2017)

120-h Track Forecast Guidance Trends Atlantic Basin

Due to model changes and other factors, **the best performing model often varies from season to season.**

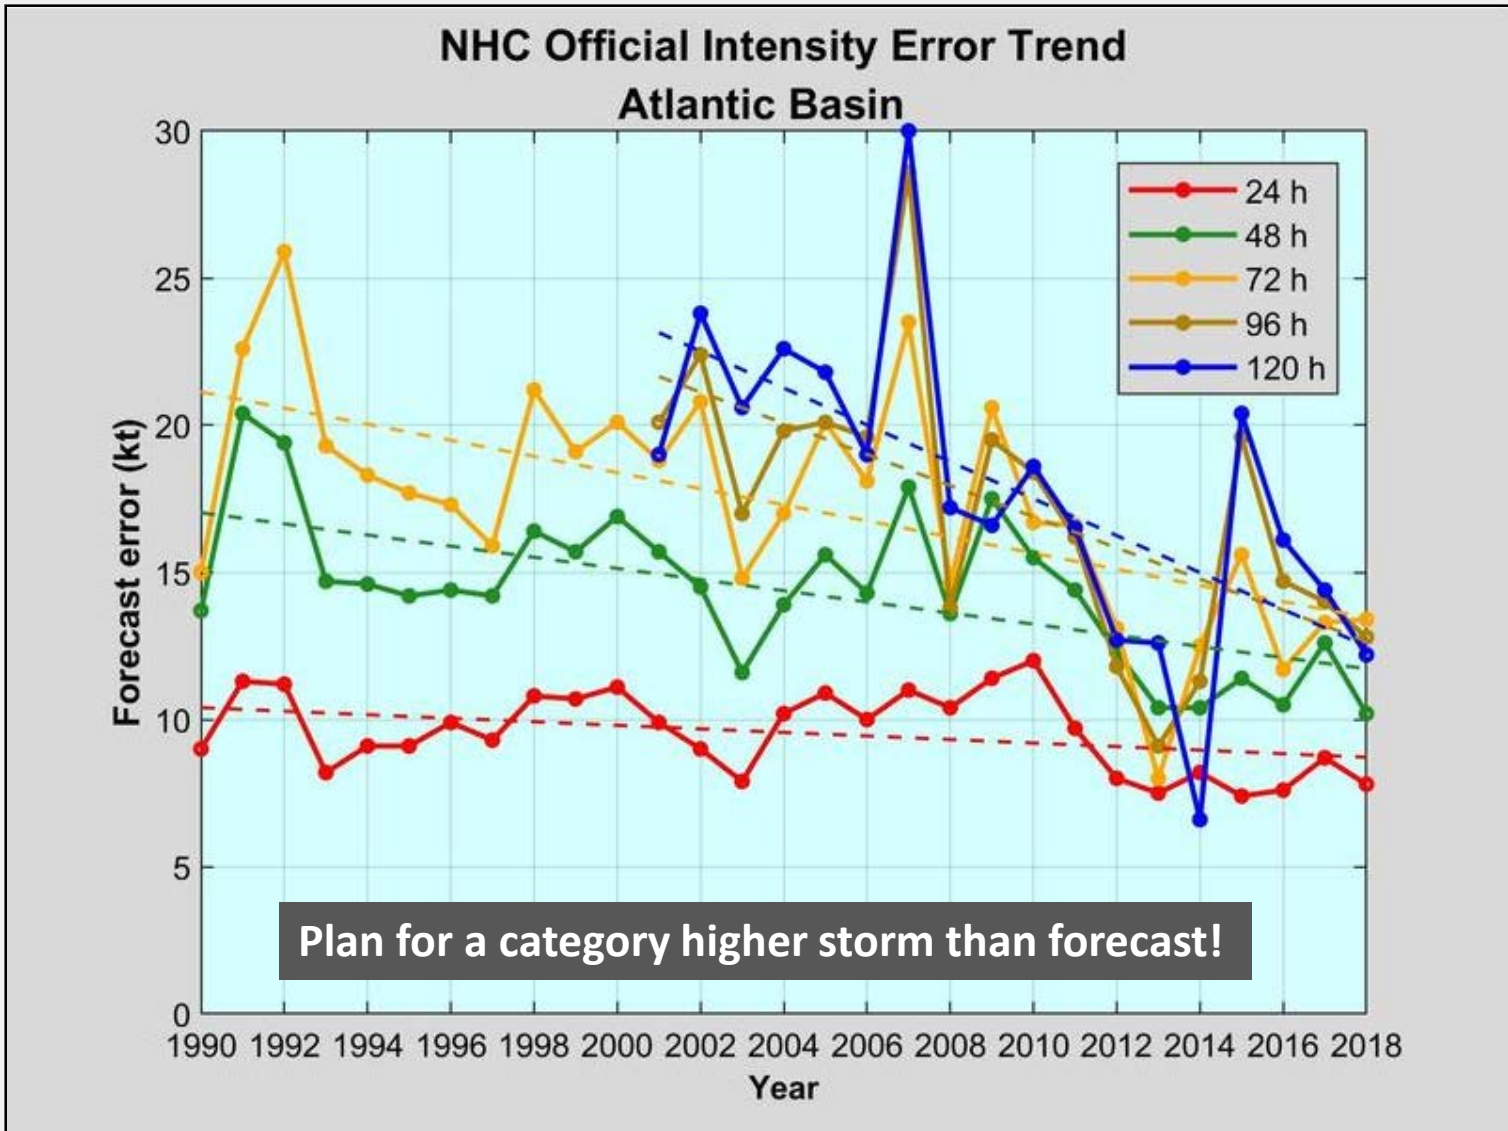

NHC Forecast Track Errors

NHC Forecast Intensity Errors

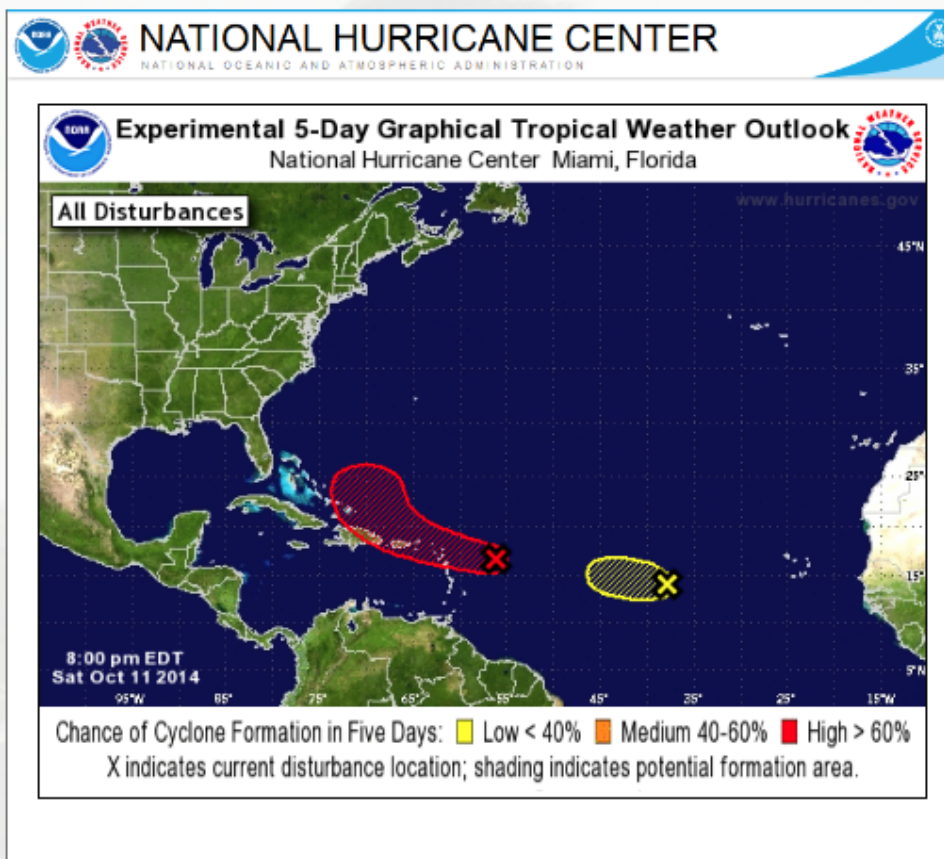

Sample 5-Day Tropical Weather Outlook

Tropical Weather Outlook Five-Day Graphic

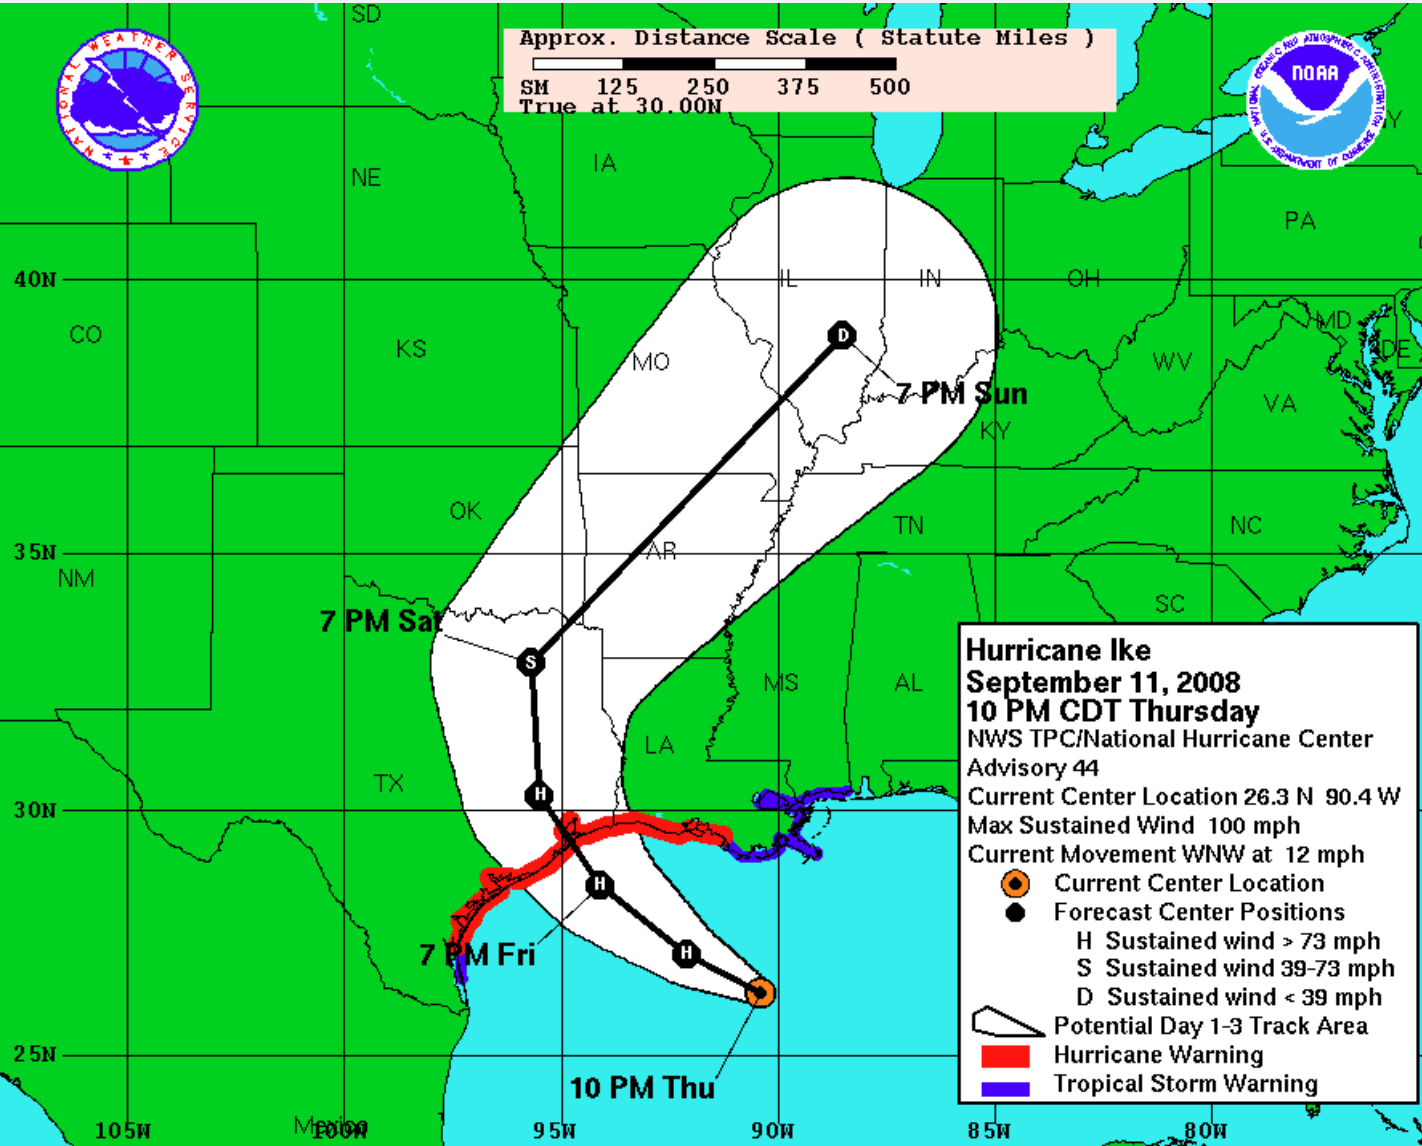

- Formation potential during the next 5 days
- Initial location of disturbance (X) indicated
- Shading represents potential formation area
- Single disturbance-based graphics available to help when areas overlap

"Cone on Uncertainty"

Cone represents where the center of the storm will be located 67% the time. Impacts can/will be observed well outside of it.

The outer edges represent the past 5-year average of track forecast errors at a particular time period.

The cone has been shrinking in size through the years as track forecasts have improved.

Expect Impacts Outside the Cone!!

“Classic” Example: Hurricane Ike

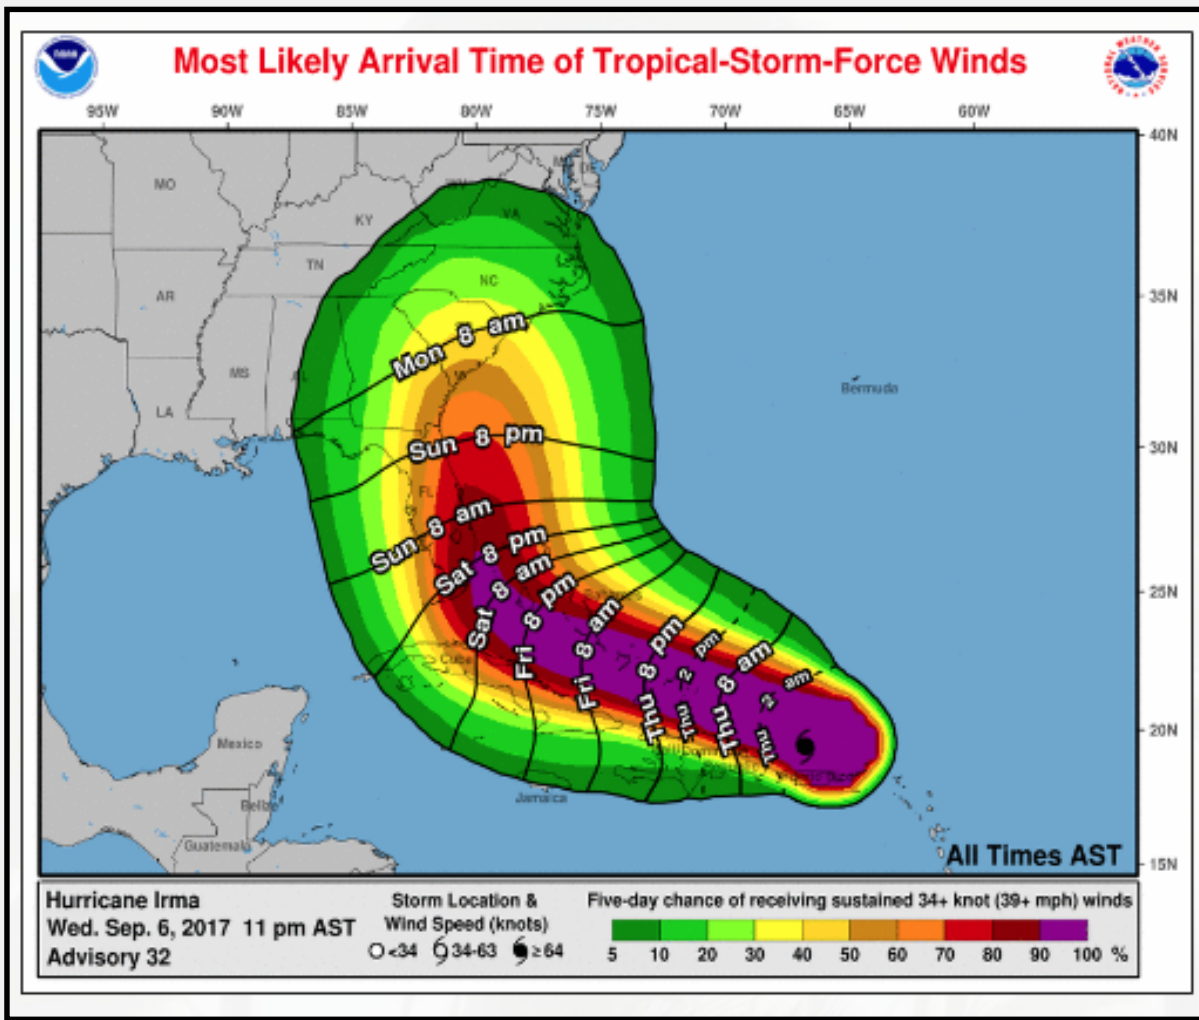

New Orleans area: Hundreds of miles from cone. Tropical Storm Warning in effect. Significant coastal flooding impacts.

Arrival Time & Probability 34+ knot winds

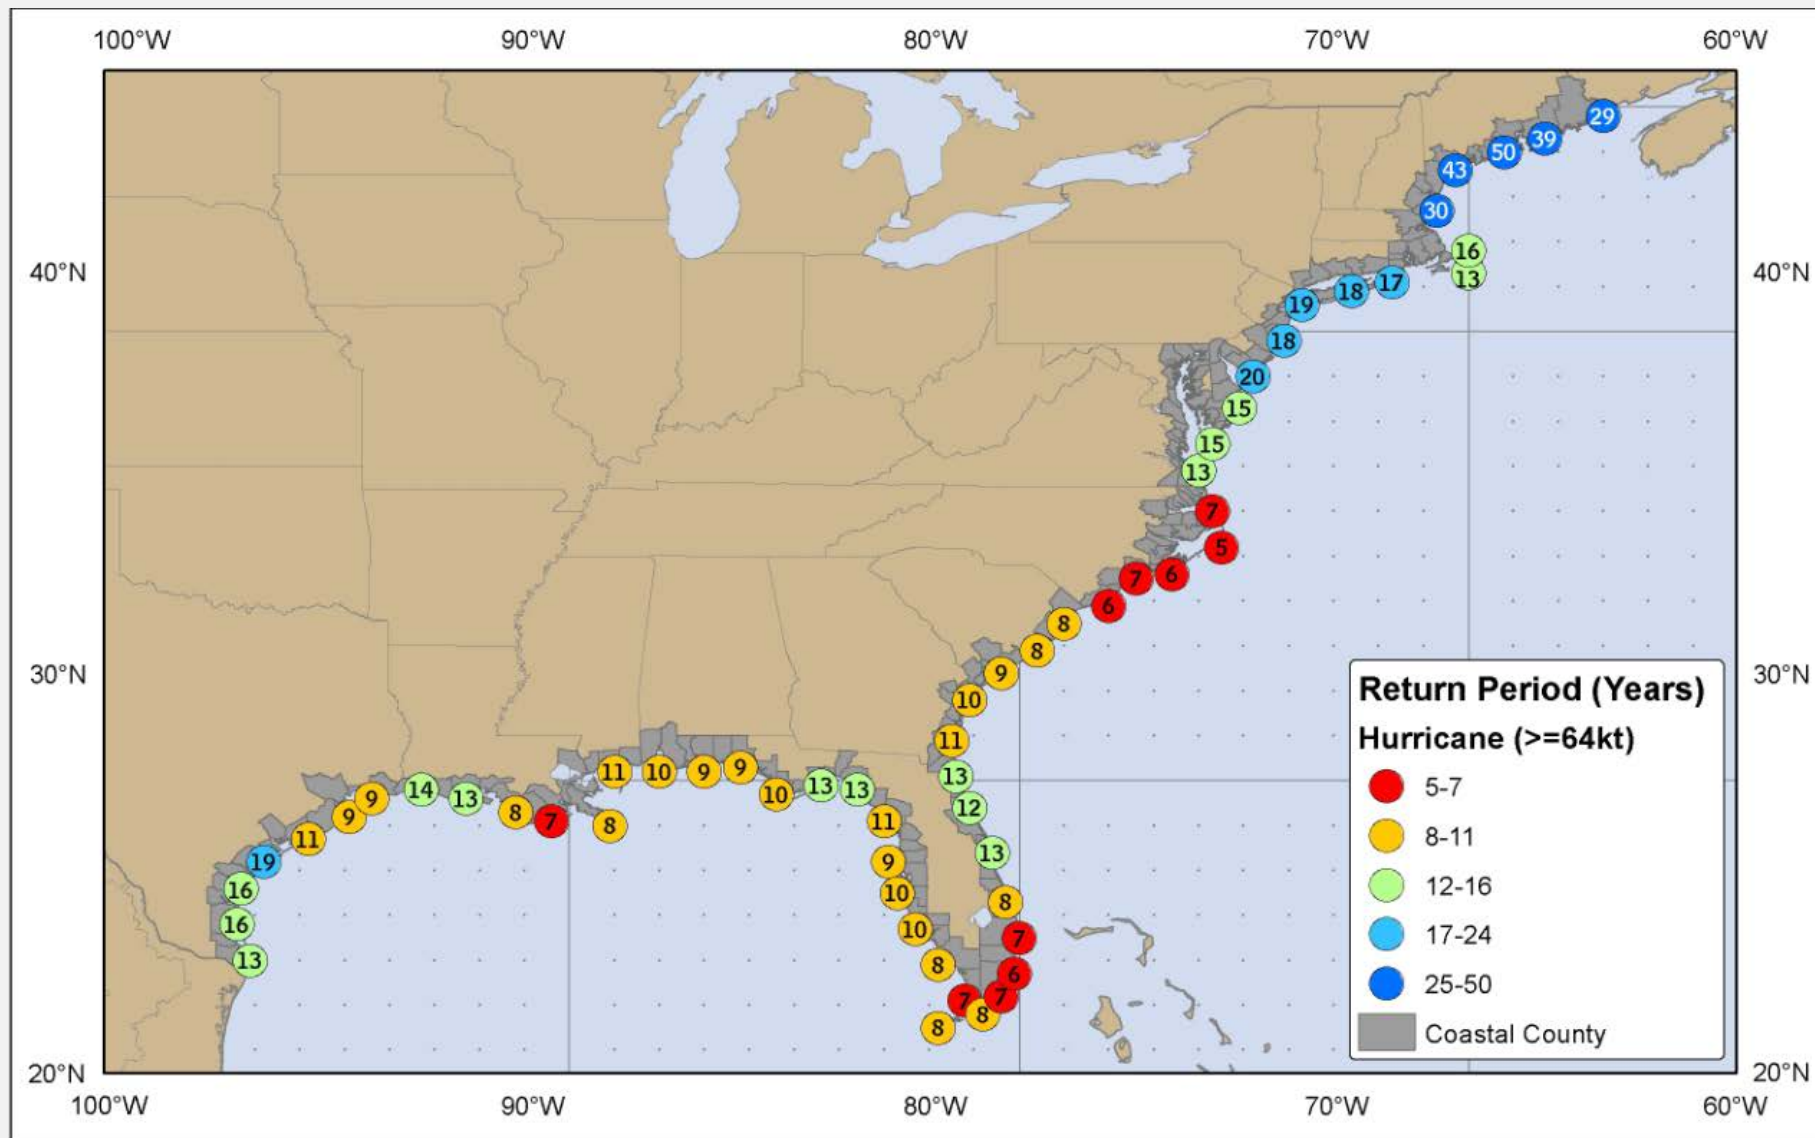

- Shows most likely arrival time of TS winds (black contours)
- Don't mistake the colors for wind swath or speed.
- They're probabilities of experiencing sustained 34+ knot winds in the next 5 days. (Outer squalls can produce earlier gusts)
- Example: Tampa area
 - 40-60% chance of 34+ knot winds.
 - Most likely arrival time of TS winds is Sun morning.

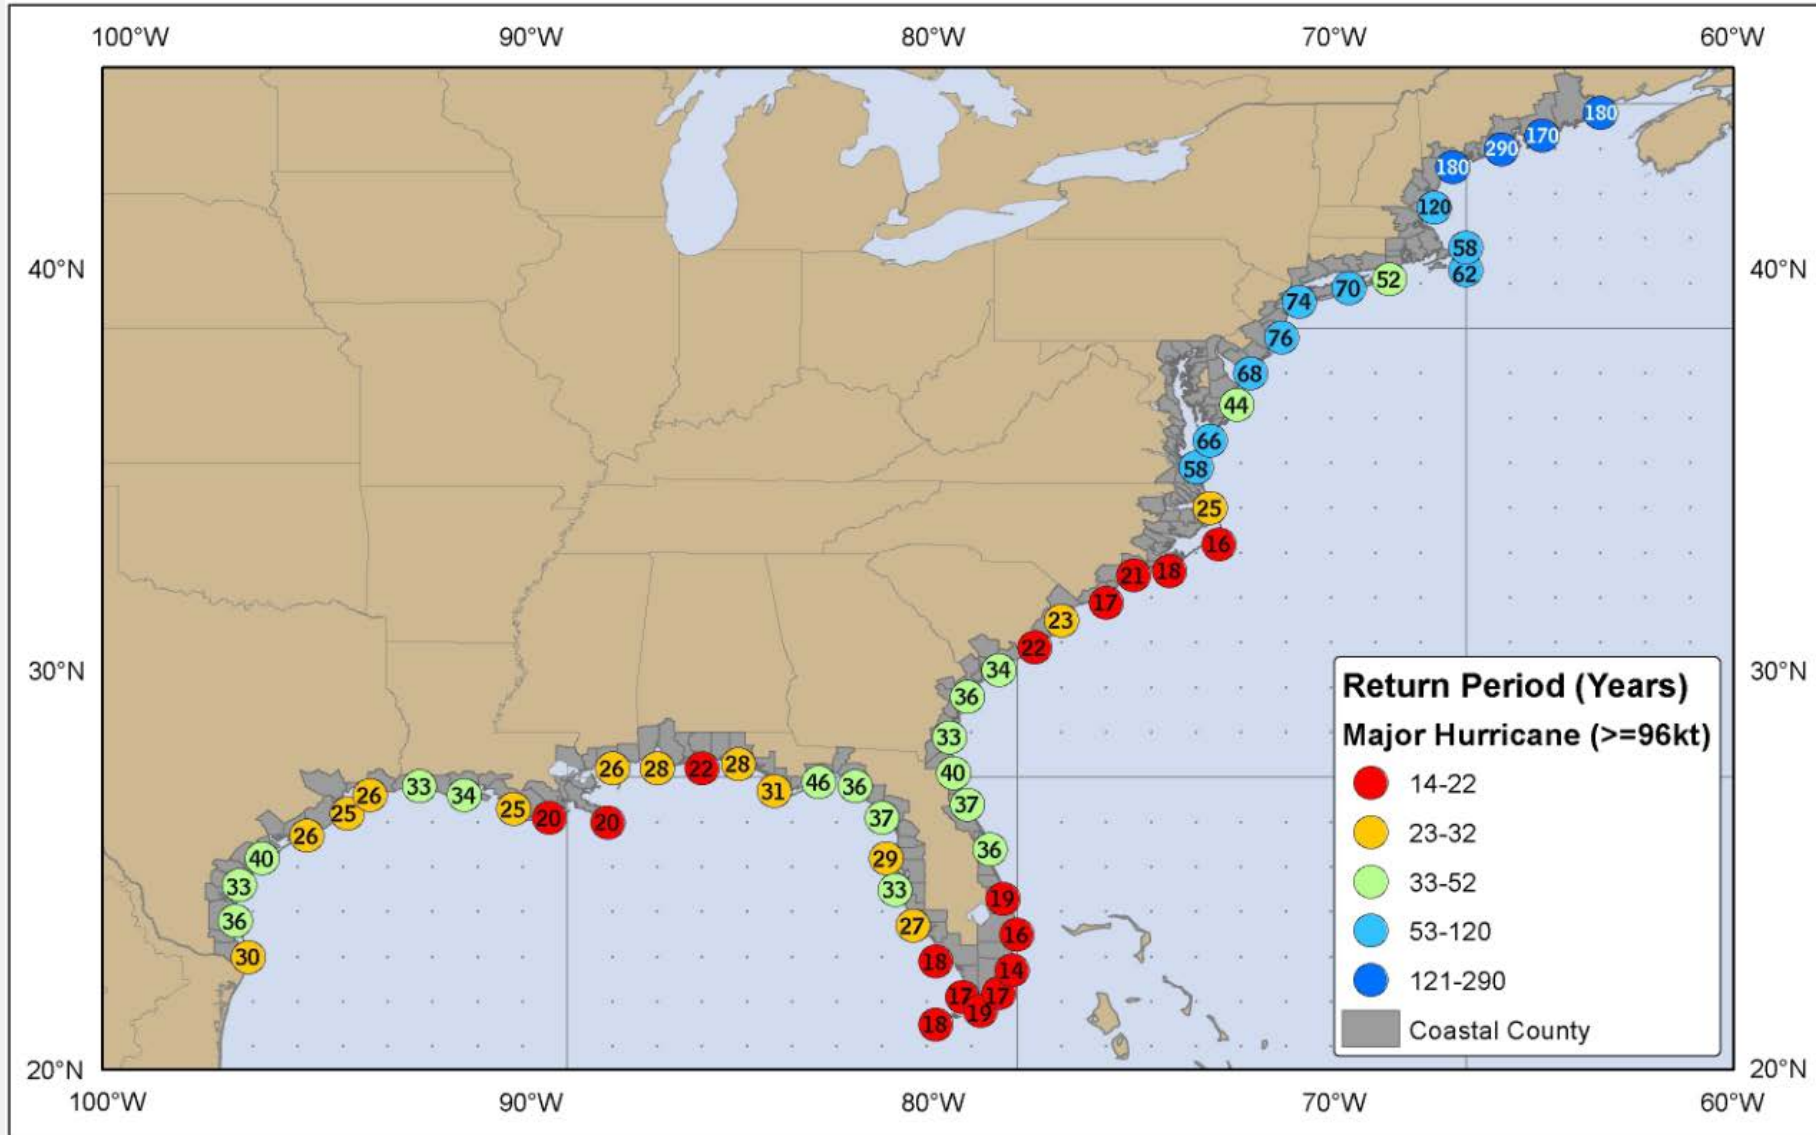

Average Hurricane Return Periods

Average Major Hurricane Return Periods (Cat 3+)

Tropical Cyclone Preparation

- **Build a kit** (whether staying or evacuating)
- **Have a plan** (where to go, where to stay IF you need to evacuate)
- **Stay aware** of what is going on in the tropics
